ABSTRACT

Aim and Objective: The present study is the morphometric evaluation of the dimensions of jugular foramen in regard to the variability in shape and size of jugular foramen and the relationship between antero-posterior diameter (APD) and mediolateral diameter (ML) of jugular foramen on each side (right & left). The dimensions of the jugular foramen are clinically important because intracranial and extracranial lesions may affect the jugular foramen. The intrinsic abnormalities and pathological processes affecting the jugular foramen are intracranial meningiomas, paragangliomas, schwannomas, metastatic lesions and infiltrative inflammatory processes from surrounding structures such as the middle ear. Other diseases associated with jugular foramen include Vernet’s syndrome and Villaret’s syndrome.

Methodology: 297 dry adult human crania of unknown sex were analyzed from the department of Anatomy, GSVM medical college, Kanpur And KGMU, Lucknow (U.P).

Anteroposterior diameter (APD) of jugular foramen: The maximum anteroposterior diameter of jugular foramen on both right and left sides were measured.

Mediolateral (ML) diameter of jugular foramen: This diameter was taken between medial most and lateral most points of jugular foramen on both right and left sides were measured.

Results: The mean anteroposterior diameter of the jugular foramen on the right and left were 15.55±2.00mm and 14.48±1.93mm. The mediolateral diameter were 9.33±1.45 mm and 7.74±1.63mm on the right and left respectively. The mean area on the right was 114.06±22.54 mm and on the left 88.90±25.23 mm.

Conclusion: These findings may be helpful for anatomists and neurosurgeons to approach the cranial base with maximum safety and minimum mortality and morbidity or clinicians in finding the appropriate diagnosis.

Key Words: Jugular foramen, Anteroposterior, Mediolateral, Human Dry Skull

INTRODUCTION

The jugular foramen is a very complicate structure to understand and access surgically; It is difficult to conceptualize because it varies in size and shape in different crania and also on two sides in the same cranium. Another point of difficulty is its formation by two bones, and the numerous nerves and venous channels that pass through it¹.

The jugular foramen lie between the occipital bone and the petrous part of the temporal bone, and can present as much elongated and irregularly shaped foramen². It is the chief route for the venous outflow from the skull. The glossopharyngeal, vagus and cranial part of the spinal accessory nerve passes through this and exit the cranial cavity³. The neural and vascular compartments are generally separated by a bony projection called the intrajugular process⁴,⁵,⁶.
Recent studies report that the foramen can have many variations in its shape and size. The so-called anomalies of the jugular bulb and glomic tumors are related to the jugular foramen, as they come in direct contact with structures that cross it, like the internal jugular vein, the internal carotid artery, and the cranial nerves. Moreover schwannomas metastatic lesions and infiltrating inflammatory processes can also modify the jugular foramen.2

A knowledge of jugular foramen is necessary in surgical conditions for microsurgical procedures, such as the lateral suboccipital access for the removal of these lesions, which were formerly thought to be very difficult to undergo an operation.3

The tumors involving jugular foramen and nearby structure require microsurgical approach to enter into this region. In most of the cases, we have to drill the nearby bones around the jugular foramen for proper exposure, but the tumor tends to alter the normal anatomy of the foramen by eroding and invading it. Therefore, it is not possible to have correct anatomic visualization of the foramen in the presence of such pathologies. Hence, a detailed knowledge of the jugular foramen is needed to all the neurosurgeons while doing surgery in this region.4

The fundamental knowledge of jugular foramen as well as symptoms of these lesions such as loss of hearing, tinnitus, otorrhea, pain, and paralysis of the facial, glossopharyngeal, vagus, and accessory nerves, is necessary. Dysfunction of these nerves is called syndrome of the jugular fossa (Vernet’s syndrome) which is characterized by: loss of taste sensation in the posterior third of the tongue, paralysis of the vocal cords and soft palate, and weakness of the Trapezius and sternocleidomastoid muscles. If tumors of the jugular foramen region extend medially to the hypoglossal canal and cause hypoglossal nerve paralysis, the clinical presentation is known as Collet-Sicard syndrome 5-12.

Latest information provides a detailed anatomy of the jugular foramen. Surgical resection is the treatment of choice in this region.6

Knowledge of Intracranial and extracranial lesions may affect the jugular foramen in addition to intrinsic abnormalities. The pathological conditions affecting JF include intrinsic abnormalities. The pathological conditions affecting JF include intracranial meningiomas, paragangliomas, glomusjugulare (jugular ganglion of the vagus nerve), schwannomas, metastatic lesions and infiltrative inflammatory processes from adjoining structures like the middle ear 14,15,16.

Recent studies report that ligation of the internal jugular is sometimes performed during radical neck dissection with the risk of venous infarction, which some adduce to be due to ligation of the dominant internal jugular vein. The 9th, 10th and 11th cranial nerves exit the cranial cavity through the JF. In the syndrome of the JF (Vernet’s syndrome), there is paralysis of the 9th, 10th and 11th cranial nerves. These, along with paralysis of the 12th cranial nerve (Villaret’s syndrome), occur with a retropharyngeal lesion invading the posterior fossa. In some instances, involvement of two or more of these nerves in other combinations is encountered (as in Jackson’s vagoaccessory hypoglossal paralysis, Schmidt’s vagoaccessory syndrome and Tapia’s vagohypoglossal palsy)17.

**MATERIALS AND METHODS**

- The present study was undertaken in adult north Indian skulls different region of north India, from different medical colleges. The total number of 297 dry adult human crania of unknown sex was analyzed from the Department of Anatomy, G SVM Medical College, Kanpur and King George Medical University, Lucknow (U.P).
- The anteroposterior, and mediolateral diameters or area of the jugular foraminal was determined. Metric measurements were taken by using digital vernier calipers. The mean, standard deviation and range of each dimension and derived index were compared. Right and left side differences were analyzed. Above all parameters were measured both side (right & left) of the jugular foramen.
- Anteroposterior diameter (APD) of jugular foramen:- maximum anteroposterior diameter of jugular foramen was measured showing no.1.
- Mediolateral (ML) diameter of jugular foramen:- This diameter was taken between medial most and lateral most points of jugular foramen showing no.2.
- Area of the foramen(A): The area of the foramen was calculated using the formula \( A = \pi \times \left\{ \frac{D \times ML}{4} \right\} \). The areas of both sides of the foramina were compared.
- Only fully ossified adult skulls were included in the present study. Skulls showing wear and tear, any fracture or pathology were excluded.

**Statistical Methods**

- The statistical analysis used for the study is SPSS (Statistical Package for Social Sciences, IBM).Version 21.

**RESULTS**

In the present study, the mean anteroposterior diameter (APD) of the jugular foramen on right and left were 15.55±2.00mm and 14.48±1.93mm, and mediolateral (ML) 9.33±1.45mm and 7.74±1.63mm on the right and left sides respectively. The mean area on the right was 114.06±22.54 mm and on the left 88.90±25.23 mm.

DISCUSSION

In the present study, the mean anteroposterior diameter of the jugular foramen on right and left were 15.55±2.00 mm and 14.48±1.93 mm, and mediolateral 9.33±1.45 mm and 7.74±1.63 mm on the right and left sides respectively. The mean area on the right was 114.06±22.54 mm and on the left 88.90±25.23 mm (Table no.1).

The comparison of the anteroposterior and mediolaterally diameter of the present study with the study done by other authors is shown in table no.2. The right foramen is larger than the left. These findings are similar to the findings of Hussain Saheb, Vijisha P, Maharshi Abhilasha, Roma Patel, Shruthi B.N, Anjali Singla, Avanish Kumar, Osunwoke E.A.O.E. Idowu shown in table no.2. Some finding is larger than the present study and some finding are smaller than present study.

CONCLUSION

This study provides detailed morphological and morphometric anatomy of the jugular foramen. Knowledge of it is very helpful for neurosurgeons dealing with a space occupying lesion in jugular foramen. These findings may be helpful for anatomists and neurosurgeons to approach the cranial base with maximum safety and minimum mortality and morbidity or clinicians in reaching the appropriate diagnosis.
