ABSTRACT

Introduction: COVID-19 is a respiratory syndrome affecting countless numbers of lives all over the world. It is reportedly caused due to the SARS-CoV-2 virus which is known to impair the lower respiratory tract causing distress. Usually affects the aged population and people with less immunity. Thus, it becomes important to make the elderly population aware of the effects of COVID infections. The study aims at analyzing the awareness of the precautions to be taken to avoid the infection among citizens.

Materials and Methods: A questionnaire was distributed through an online Google form link to about 100 people, who are more than 50 years of age. The study population was asked to fill out the online form after reading each question thoroughly.

Results: The results were collected and the data was analyzed using SPSS version 20. From the survey, it is evident that most of the elderly people are aware of the importance of self-isolation as a preventive measure to fight COVID infection.

Conclusion: This study gives an insight into the public perception towards the awareness of self-isolation to fight COVID-19 among elderly people.

Key Words: COVID-19, Elderly people, Public perception, Self isolation, Quarantine, Survey.

INTRODUCTION

COVID-19 is a respiratory syndrome affecting countless numbers of lives all over the world. Elderly people can stay at the home and home quarantine themselves.1,2. They should contact medical advisors if required and should stay isolated at home3,4. COVID-19 is a viral infectious disease that can infect mostly the elderly people due to their low immunity power5. Old age people are already prone to increased risk of cardiovascular, autoimmune, and mental health problems6,7. When seeing their vulnerability it is better to avoid going out and meeting people avoid hand shaking8,9. COVID infection is exhibited by respiratory illness, fatigue, fever, sore throat, and tiredness10,11. Elderly people are more prone to get infected from COVID-19 Human coronavirus attacks the upper respiratory tract ranging from mild to moderate severity12,13. It is studied that people with low immunity14,15 power are more prone to get infected16,17. COVID-19 prone areas are kept under quarantine and long lockdown. They have closed all the schools, colleges, public places, and companies, in which Tamil Nadu has the highest cases compared to other states18,19. Till now, there are no vaccines discovered to cure COVID-19. But there are necessarily strict precautions to be taken20,21. COVID-19 cannot be transmitted in hot climates. As a precaution people are advised to wear masks and gloves. They are also advised to maintain social distance use alcohol-based hand sanitizer. Avoid touching, hugging, and handshaking with other people.22,23

In this current situation, when there are no treatment methods or vaccines available to protect people, it becomes very important to prevent the community from diseases. Having known that the sector of people who are prone are elderly and sick people, it becomes important, that a proper awareness to be created to keep them healthy.24
This study is done in order to spread awareness on self-isolation as a preventive measure to fight COVID-19 infection among the elderly population. It mainly focuses on analyzing the general public’s perspective about the precautions they should take.

**MATERIALS AND METHODS**

**Study Design**

A survey was conducted among elderly people (age more than 50) to evaluate the knowledge, awareness, and perception of self-isolation procedures to be followed during a pandemic. The sampling method is a simple random sampling method. The sample size of the study is 165. The participants did the survey voluntarily and no incentives were given to them. Ethical approval and informed consent from the participants were obtained. The study was conducted in the month of May, 2020.

**Survey Instrument**

The survey instrument which was a questionnaire was prepared after an extensive review of the existing literature. The questionnaire was reviewed and amendments were made to improve clarity of the questions to eliminate ambiguous responses. The questionnaire consisted of a total of 12 questions. The questionnaire was shared to the participants using an online survey platform using the following link “https://docs.google.com/forms/d/e/1FAIpQLSdEHu-eiWv1BFmGilXloJaHftzJEPRQZIyTvBo-B0Hp8y7dw/viewform?usp=sf_link”

**Data Analysis**

Only completed surveys were taken for analysis and the incomplete surveys were eliminated. The statistical test used is descriptive statistics. All the responses obtained were tabulated and the reliability of the data was checked. A bar graph with a frequency table was prepared and analyzed for each question using SPSS data analysis software.

A questionnaire containing questions related to creating awareness on the increasing spread of COVID infection was distributed through an online Google forms link to about 100 elderly people. The study population was asked to fill out the online form after reading each question thoroughly. The results were collected and the data was analyzed using SPSS version 20.

**RESULTS**

Figure 1: Bar chart showing the correlation between gender and opinion on whether the lockdown is essential. Bar graph representing the individual opinion on whether the lockdown is essential based on gender. X-axis represents Gender, Y-axis represents individuals who are aware (blue) and unaware (red). 94 out of 97 male participants, 65 out of 68 female participants feel lockdown is essential. Gender doesn’t seem to influence opinion towards keeping them safe. Pearson’s Chi-square value: 0.16, DF - 1, p-value= 0.899 (>0.05), and it was not statistically significant.

Figure 2: Figure represents the distribution of participants based on their opinion towards maintaining social distancing among friends and family members, where 85.05% (blue) of the study participants feel that social distancing to be maintained even among friends and family members and 14.95% (red) of them feel that it is not necessary.

Figure 3: Bar chart showing the correlation between gender and whether they are practicing self-isolation protocols strictly.
Bar graph represents the individual opinion on whether they are practicing self-isolation protocols based on gender. X-axis represents Gender, Y-axis represents individuals who are practicing (blue) and not practicing (red). 88 out of 97 male participants and 64 out of 68 female participants agree that they strictly follow self-isolation protocols. Gender doesn’t seem to influence the safety protocol. Pearson’s Chi-square analysis = 0.775, DF- 1, p-value= 0.379 (>0.05), and it was not statistically significant.

Figure 4: Bar chart showing the correlation between gender and whether they are wearing masks when they go out. The bar graph represents the individual opinion on whether they wear a mask while going out based on gender. X-axis represents Gender, Y-axis represents individuals who are aware (blue) and unaware (red). 90 out of 97 male participants, 64 out of 68 female participants agree that they strictly wear masks while going out. Gender doesn’t seem to influence the safety protocol. Pearson’s Chi-square analysis = 1.274, DF- 1, P-value= 0.259 (>0.05), and it was not statistically significant.

Figure 5: Bar chart showing the correlation between gender and the opinion on being careful as they are more prone to infection. Bar graph represents the individual opinion on whether they are aware that they are more prone to infection as they are elderly based on gender. X-axis represents Gender, Y-axis represents individuals who are aware (blue) and unaware (red). 93 out of 97 male participants and 64 out of 68 female participants agree that they are more prone to infection. Pearson’s Chi-square analysis = 0.240, DF- 1, P-value = 0.624 (>0.05), and it was not statistically significant.

DISCUSSION

From the study population (100%) around 70% answered positively when asked whether lockdown is essential (Fig. 1), thus in the bar graph representing Chi-square analysis between gender and their opinion towards lockdown 38 males and 32 females supported for lockdown, the P-value was 0.899 and it was not statistically significant. According to the previous, the elderly are more prone to get infected because of their low immune. About 90.3% of the study population are aware that they should not go out and get contacted with other people, and must follow social distancing (Fig. 2). About 95.2% of the participants answered positively when asked whether while sleeping also social distancing is important. According to the article elderly people are more prone to get infected because many have cardiovascular-related problems. When asked about the self-isolation protocols around 92.1% of the respondents answered positively (Fig. 3). In the bar graph representing Chi-square analysis between gender and awareness on practicing self-isolation, 50 male participants and 45 female participants were aware
of it. The P-value was 0.375 and it was not statistically significant. The study population was asked a question whether they feel lonely, about 93.3% of the population answered that they feel lonely, but at the same time understood the need of the hour too. According to the previous study, elderly people usually feel lonely in some unstable situations. A question was raised on whether they wear masks when they go out, to which 93.3% of respondents answered positively (Fig. 4). In the bar graph representing Chi-square analysis between gender and awareness on wearing masks, about 50 males and 42 females were aware of it, The P-value was 0.259 and it was not statistically significant. A question was asked whether elderly people have high chances to get infected and around 95.2% of the study population answered that older people have more chances to get infected due to weak immune systems (Fig. 5). In the bar graph representing Chi-square analysis between gender and awareness of high risk of being infected, 49 males and 42 females were aware of it, the P-value was 0.624 and it was not statistically significant. According to the previous study, elderly people have less blood flow rate and RBC count as their age increases and might be a reason for making them prone to various infections. About 92.7% of the population answered positively when asked about whether they teach or instruct their friends and family members about the safety measures they should take to avoid infection (Fig. 6). In the bar graph representing Chi-square analysis between gender and willingness to spread awareness 52 males and 42 females were interested to spread awareness. The P-value was 0.624 and it was not statistically significant. When asked whether lockdown prevails in our country, about 95.1% of the population answered that they are well aware of the government instructed lockdown. According to the previous article, elderly people are more sensitive and always want to know things going around. When asked about whether the survey was useful around 93.9%. The study population said it was very useful.

The future scope of this study focuses on helping the population in understanding the public perception regarding the self-isolation of elderly people. It also focuses on ensuring the knowledge of various preventive measures that can be taken in order to prevent the acquisition of the virus thereby leading to the betterment of health and lifestyle of the elderly population.

**CONCLUSION**

COVID-19 is thought to infect host cells through ACE-2 to cause COVID-19 while also damaging to myocardium. Self-isolation will affect elderly individuals whose social contact is out of the home, such as the daycare venues, community centers, and places of worship. Elderly people should remain home, have groceries and vital medications delivered, and should avoid social contact with family and friends. Self-isolation among elderly people is a serious public health concern because of their heightened risk of cardiovascular, autoimmune, and mental health problems. This study gives an insight of the public perception towards the awareness of self-isolation among elderly people.
